# Zero Knowledge Proofs

- Proofs that yield nothing beyond the validity of an assertion
- Examples of assertions
  - I know the discrete log of a group element wrt a generator
  - I know an isomorphism between two graphs  $G_1, G_2$
- Proofs are a sequence of statements each of which is an axiom or follows from axioms via derivation rules
  - Traditional proofs do not have explicit provers and verifiers
- ZKPs involve explicit interaction between prover and verifier
- Prover and verifier will be modeled as algorithms or machines
  - Verifier is assumed to be probabilistic polynomial-time (PPT)
  - Prover may or may not be PPT

# Knowledge vs Information

- In information theory, entropy is used to quantify information
- Entropy of a discrete random variable  $X$  defined over an alphabet  $\mathcal{X}$  is

$$H(X) = - \sum_{x \in \mathcal{X}} p(x) \log p(x)$$

- Knowledge is related to computational difficulty, whereas information is not
  - Suppose Alice and Bob know Alice's public key
  - Alice sends her private key to Bob
  - Bob has not gained new information (in the information-theoretic sense)
  - But Bob now knows a quantity he could not have calculated by himself
- Knowledge is related to publicly known objects, whereas information relates to private objects
  - Suppose Alice tosses a fair coin and sends the outcome to Bob
  - Bob gains one bit of information (in the information-theoretic sense)
  - We say Bob has not gained any knowledge as he could have tossed a coin himself

# Modeling Assertions and Proofs

- The complexity class  $\mathcal{NP}$  captures the asymmetry between proof generation and verification
- A language is a subset of  $\{0, 1\}^*$
- Each language  $L \in \mathcal{NP}$  has a polynomial-time verification procedure for proofs of statements “ $x \in L$ ”
  - Example:  $L$  is the encoding of pairs of finite isomorphic graphs
- Let  $R \subset \{0, 1\}^* \times \{0, 1\}^*$  be a relation
- $R$  is said to be polynomial-time-recognizable if the assertion “ $(x, y) \in R$ ” can be checked in time  $\text{poly}(|x|, |y|)$
- Each  $L \in \mathcal{NP}$  is given by a PTR relation  $R_L$  such that

$$L = \{x \mid \exists y \text{ such that } (x, y) \in R_L\}$$

and  $(x, y) \in R_L$  only if  $|y| \leq \text{poly}(|x|)$

- Any  $y$  for which  $(x, y) \in R_L$  is a proof of the assertion “ $x \in L$ ”

# Interactive Proof Systems

- Let  $\langle A, B \rangle(x)$  denote the output of  $B$  when interacting with  $A$  on common input  $x$
- Output 1 is interpreted as “accept” and 0 is interpreted as “reject”

## Definition

A pair of interactive machines  $(P, V)$  is called an **interactive proof system for a language  $L$**  if machine  $V$  is polynomial-time and the following conditions hold:

- **Completeness:** For every  $x \in L$ ,

$$\Pr[\langle P, V \rangle(x) = 1] \geq \frac{2}{3}$$

- **Soundness:** For every  $x \notin L$  and every interactive machine  $B$ ,

$$\Pr[\langle B, V \rangle(x) = 1] \leq \frac{1}{3}$$

- Remarks

- Soundness condition refers to any possible prover while completeness condition refers only to the prescribed prover
- Prescribed prover is allowed to fail with probability  $\frac{1}{3}$
- Arbitrary provers are allowed to succeed with probability  $\frac{1}{3}$
- These probabilities can be made arbitrarily small by repeating the interaction

## Interactive Proof Example

- Suppose Peggy claims that Pepsi in large bottles tastes different than Pepsi in small bottles
- Victor challenges Peggy to prove her claim
- Peggy and Virgil execute the following protocol
  - Victor asks Peggy to leave the room
  - He selects either a large bottle or a small bottle randomly and pours some Pepsi into a glass
  - Peggy is called into the room and asked to tell which bottle the Pepsi came from by tasting it
  - Victor records Peggy's response and the above steps are repeated one more time
  - If Peggy answers correctly both times, Victor accepts the claim
- If the claim is correct,  $\Pr[\langle P, V \rangle(x) = 1] = 1 \geq \frac{2}{3}$
- If the claim is wrong,  $\Pr[\langle P, V \rangle(x) = 1] = \frac{1}{4} \leq \frac{1}{3}$

# Interactive Proof for Graph Non-Isomorphism

- Graphs  $G_1 = (V_1, E_1)$  and  $G_2 = (V_2, E_2)$  are isomorphic if there exists a bijection  $\pi : V_1 \mapsto V_2$  such that  $(u, v) \in E_1 \iff (\pi(u), \pi(v)) \in E_2$
- Graphs  $G_1$  and  $G_2$  are non-isomorphic if no such bijection exists
- Prover and verifier execute the following protocol
  - Verifier picks  $\sigma \in \{1, 2\}$  randomly and a random permutation  $\pi$  from the set of all permutations over  $V_\sigma$
  - Verifier calculates  $F = \{(\pi(u), \pi(v)) \mid (u, v) \in E\}$  and sends the graph  $G' = (V_\sigma, F)$  to prover
  - Prover finds  $\tau \in \{1, 2\}$  such that  $G'$  is isomorphic to  $G_\tau$  and sends  $\tau$  to verifier
  - If  $\tau = \sigma$ , verifier accepts claim. Otherwise, it rejects.
- Remarks
  - Verifier is a PPT machine but no known PPT implementation for prover
  - If  $G_1$  and  $G_2$  are not isomorphic, then verifier always accepts
  - If  $G_1$  and  $G_2$  are isomorphic, then verifier rejects with probability at least  $\frac{1}{2}$
  - Repeated interactions can make false acceptance probability arbitrarily small

# Zero Knowledge Interactive Proofs

- Consider an interactive proof system  $(P, V)$  for a language  $L$ 
  - In an interactive proof, we need to guard against a malicious prover
  - To guarantee zero knowledge, we need to guard against a malicious verifier
- Recall that knowledge is related to computational difficulty
- Informal definition
  - An interactive proof system is **zero knowledge** if whatever can be efficiently computed **after interaction** with  $P$  on input  $x$  can also be efficiently computed from  $x$  (**without interaction**)
- Formal definition (ideal)
  - We say  $(P, V)$  is **perfect zero knowledge** if for every PPT interactive machine  $V^*$  there exists a PPT algorithm  $M^*$  such that for every  $x \in L$  the random variables  $\langle P, V^* \rangle(x)$  and  $M^*(x)$  are **identically distributed**
    - $M^*$  is called a **simulator** for the interaction of  $V^*$  with  $P$
- Unfortunately, the above definition is too strict
- A relaxed definition is used instead

# Perfect Zero Knowledge

## Definition

Let  $(P, V)$  be an interactive proof system for a language  $L$ . We say that  $(P, V)$  is **perfect zero knowledge** if for every PPT interactive machine  $V^*$  there exists a PPT algorithm  $M^*$  such that for every  $x \in L$  the following two conditions hold:

1. With probability at most  $\frac{1}{2}$ , machine  $M^*$  outputs a special symbol  $\perp$
2. Let  $m^*(x)$  be the random variable describing the distribution of  $M^*(x)$  conditioned on  $M^*(x) \neq \perp$ . Then the random variables  $\langle P, V^* \rangle(x)$  and  $m^*(x)$  are **identically distributed**

- Remarks

- $M^*$  is called a **perfect simulator** for the interaction of  $V^*$  with  $P$
- By repeated interactions, the probability that the simulator fails to generate the identical distribution can be made negligible
- **Alternative formulation:** Replace  $\langle P, V^* \rangle(x)$  with  $\text{view}_{V^*}^P(x)$ 
  - A verifier's view consists of messages it receives and any randomness it generates
  - Simulator  $M^*$  has to change accordingly

# ZK Proof for Graph Isomorphism

- An isomorphism  $\phi$  between graphs  $G_1 = (V_1, E_1)$  and  $G_2 = (V_2, E_2)$  exists
- Prover and verifier execute the following protocol
  - Prover picks a random permutation  $\pi$  from the set of permutations of  $V_2$
  - Prover calculates  $F = \{(\pi(u), \pi(v)) \mid (u, v) \in E_2\}$  and sends the graph  $G' = (V_2, F)$  to verifier
  - Verifier picks  $\sigma \in \{1, 2\}$  randomly and sends it to prover
  - If  $\sigma = 2$ , then prover sends  $\pi$  to the verifier. Otherwise, it sends  $\pi \circ \phi$  to the verifier where  $(\pi \circ \phi)(v)$  is defined as  $\pi(\phi(v))$
  - If the received mapping is an isomorphism between  $G_\sigma$  and  $G'$ , the verifier accepts. Otherwise, it rejects
- Remarks
  - Verifier is a PPT machine. If  $\phi$  is known to prover, it is a PPT machine
  - If  $G_1$  and  $G_2$  are isomorphic, then verifier always accepts
  - If  $G_1$  and  $G_2$  are not isomorphic, then verifier rejects with probability  $\frac{1}{2}$
  - The prover is perfect zero knowledge (to be argued)

# Simulator for Graph Isomorphism Transcript

- For an arbitrary PPT verifier  $V^*$ , view $_{V^*}^P(x) = \langle G', \sigma, \psi \rangle$  where  $\psi$  is an isomorphism between  $G_\sigma$  and  $G'$
- The simulator  $M^*$  uses  $V^*$  as a subroutine
- On input  $(G_1, G_2)$ , simulator randomly picks  $\tau \in \{1, 2\}$  and generates a random isomorphic copy  $G''$  of  $G_\tau$ 
  - Note that  $G''$  is identically distributed to  $G'$
- Simulator gives  $G''$  to  $V^*$  and receives  $\sigma \in \{1, 2\}$  from it
  - $V^*$  is asking for an isomorphism from  $G_\sigma$  to  $G''$
- If  $\sigma = \tau$ , then the simulator can provide the isomorphism  $\pi : G_\tau \mapsto G''$
- If  $\sigma \neq \tau$ , then the simulator outputs  $\perp$
- If the simulator does not output  $\perp$ , then  $\langle G'', \tau, \pi \rangle$  is identically distributed to  $\langle G', \sigma, \psi \rangle$
