#### EE 720: An Introduction to Number Theory and Cryptography (Spring 2018)

Lecture 11 — February 14, 2018

Instructor: Saravanan Vijayakumaran Scribe: Saravanan Vijayakumaran

#### 1 Lecture Plan

- Define CCA-security
- Describe the padding oracle attack

## 2 Chosen-Ciphertext Attack Security

- Previously, we considered ciphertext-only attacks and chosen-plaintext attacks. Known-plaintext attacks are weaker than chosen-plaintext attacks, so an encryption scheme which is CPA-secure will also be KPA-secure.
- We now consider *chosen-ciphertext attacks*. Here, the adversary has access to a decryption oracle  $Dec_k(\cdot)$  which decrypts ciphertexts chosen by the adversary. The adversary is not allowed to send the ciphertext exchanged between the honest parties to the decryption oracle.
- For a formal definition of the CCA threat model, consider the CCA indistinguishability experiment  $PrivK_{A,\Pi}^{cca}(n)$ :
  - 1. A key k is generated by running  $Gen(1^n)$ .
  - 2. The adversary  $\mathcal{A}$  is given  $1^n$  and oracle access to  $\operatorname{Enc}_k(\cdot)$  and  $\operatorname{Dec}_k(\cdot)$ . It outputs a pair of messages  $m_0, m_1 \in \mathcal{M}$  with  $|m_0| = |m_1|$ .
  - 3. A uniform bit  $b \in \{0,1\}$  is chosen. Ciphertext  $c \leftarrow \text{Enc}_k(m_b)$  is computed and given to A. c is called the *challenge ciphertext*.
  - 4. The adversary  $\mathcal{A}$  continues to have oracle access to  $\operatorname{Enc}_k(\cdot)$  and  $\operatorname{Dec}_k(\cdot)$ , but is not allowed to query the latter on the challenge ciphertext itself. Eventually, A outputs a bit b'.
  - 5. The output of the experiment is defined to be 1 if b' = b, and 0 otherwise. If output is 1, we say that A succeeds.

**Definition.** A private-key encryption scheme  $\Pi = (Gen, Enc, Dec)$  has indistinguishable encryptions under a chosen-ciphertext attack, or is CCA-secure, if for all probabilistic polynomial-time adversaries A there is a negligible function negl such that, for all n,

$$\Pr\left[\textit{PrivK}^{\textit{cca}}_{\mathcal{A},\Pi}(n) = 1\right] \leq \frac{1}{2} + \textit{negl}(n).$$

• None of the encryption schemes we have seen so far is CCA-secure. Consider the CPA-secure scheme where  $\operatorname{Enc}_k(m) = \langle r, F_k(r) \oplus m \rangle$ . Consider the following adversary  $\mathcal A$  in the CCA indistinguishability experiment.

- 1.  $\mathcal{A}$  chooses  $m_0 = 0^n$  and  $m_1 = 1^n$ .
- 2. Upon receiving the challenge ciphertext  $c = \langle r, s \rangle = \langle r, F_k(r) \oplus m_b \rangle$ ,  $\mathcal{A}$  asks for the decryption of  $c' = \langle r, s' \rangle = \langle r, s \oplus 10^{n-1} \rangle$  i.e. the bit n+1 in c is flipped.
- 3. The oracle answers with  $m' = s' \oplus F_k(r) = F_k(r) \oplus m_b \oplus 10^{n-1} \oplus F_k(r) = m_b \oplus 10^{n-1}$ .
- 4. m' is  $10^{n-1}$  if b=0 and  $01^{n-1}$  if b=1. So the adversary succeeds with probability 1.

## 3 Padding Oracle Attack

- Do chosen-ciphertext attacks model any real-world attack? The answer is yes. Padding oracle attacks are one such example.
- Recall the CBC block cipher mode used encrypt plaintext whose length is longer than the block length of a block cipher.
  - Let  $m = m_1, m_2, \dots, m_l$  where  $m_i \in \{0, 1\}^n$ .
  - Let F be a length-preserving block cipher with block length n.
  - A uniform initialization vector (IV) of length n is first chosen.
  - $-c_0 = IV$ . For  $i = 1, \ldots, l, c_i := F_k(c_{i-1} \oplus m_i)$ .
  - For  $i = 1, 2, ..., l, m_i := F_k^{-1}(c_i) \oplus c_{i-1}$ .
- The above scheme assumes that the plaintext length is a multiple of n. The plaintext is usually padded to satisfy this constraint. For convenience we will refer to the original plaintext as the message and the result after padding as the encoded data.
- A popular padding scheme is the PKCS #7 padding.
  - Assume that the original message m has an integral number of bytes. Let L be the blocklength of the block cipher in bytes.
  - Let b denote the number of bytes required to be appended to the original message to make the encoded data have length which is a multiple of L. Here, b is an integer from 1 to L (b = 0 is not allowed).
  - We append to the message the integer b (represented in 1 byte) repeated b times. For example, if 4 bytes are needed then the 0x04040404 is appended. Note that L needs to be less than 256. Also, if the message length is already a multiple of L, then L bytes need to be appended each of which is equal to L.
- The encoded data is encrypted using CBC mode. When decrypting, the receiver first applies CBC mode decryption and then checks that the encoded data is correctly padded. The value b of the last byte is read and then the final b bytes of the encoded data is checked to be equal to b.
- If the padding is incorrect, the standard procedure is to return a "bad padding" error. The presence of such an error message provides the an adversary with a partial decryption oracle. While this may seem like meaningless information, it enables the adversary to completely recover the original message for any ciphertext of its choice.
- See pages 99–100 for a complete description of the attack.
- One solution is to use message authentication codes.
